About this Document

This document provides a developer overview of the OpenID Connect protocol and provides instructions for an Application Developer to implement OpenID Connect with PingFederate. Two walkthroughs are provided to demonstrate the OpenID Connect Basic Client Profile and the OpenID Connect Implicit Client Profile.

This is targeted to developers; however, the content will be relevant for infrastructure owners to understand the OpenID Connect concepts.

Explanations and code examples are provided for "quick win" integration efforts. As such, they are incomplete and meant to complement existing documentation and specifications.

This document assumes familiarity with the OpenID Connect protocol and the OAuth 2.0 protocol. For more information about OAuth 2.0 and OpenID Connect, refer to:

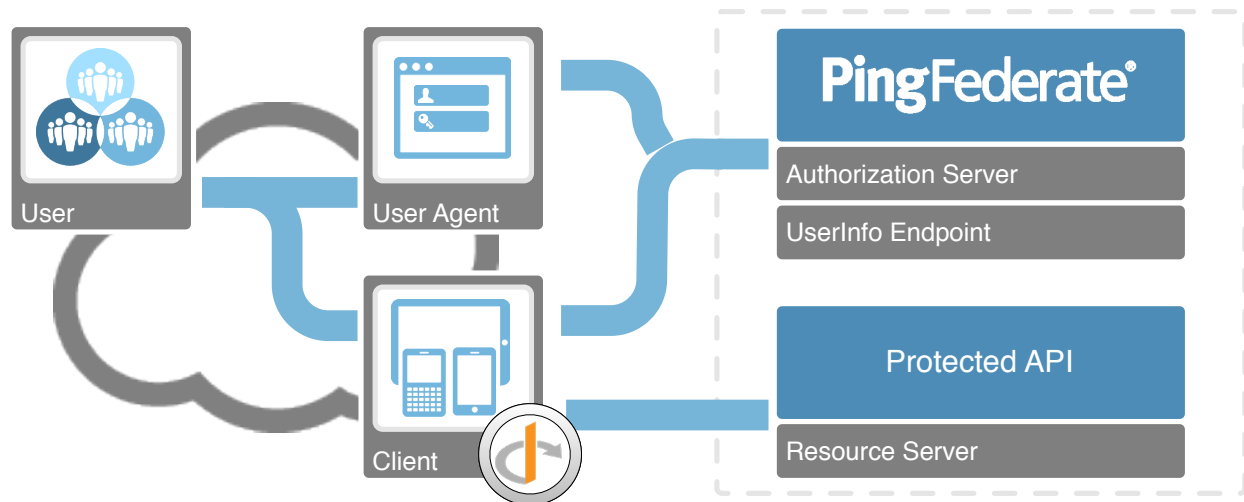

- [PingFederate Administrator's Manual](#)
- [OpenID Connect Specification](#)
- [OAuth 2.0 developers guide](#)
- [OAuth 2.0 RFC 6749](#)

Note:	This document explains a number of manual processes to request and validate the OAuth tokens. While the interactions are simple, PingFederate is compatible with many 3 rd party OAuth client libraries that may simplify development effort.
-------	--

Section One – Getting Started

1 Overview

1.1 OpenID Connect Overview

The OpenID Connect protocol is built upon the OAuth 2.0 protocol. The Connect protocol provides two new concepts to add an Identity layer on top of the OAuth 2.0 authorization framework. These concepts are an OpenID Connect “ID token,” which contains information around the user’s authenticated session, and the UserInfo endpoint, which provides a means for the client to retrieve additional attributes about the user.

OpenID Connect uses the same actors and processes to get an ID token and protect the UserInfo endpoint as the OAuth 2.0 framework.

1.2 Application Developer Considerations

There are three main actions an application developer needs to handle to implement OpenID Connect:

1. Get an OpenID Connect id_token
By leveraging an OAuth2 grant type, an application will request an OpenID Connect id_token.
2. Validate the id_token
Validate the id_token to ensure it originated from a trusted issuer and that the contents have not been tampered with during transit.

3. Retrieve profile information from the UserInfo endpoint
Using the OAuth2 access token, access the UserInfo endpoint to retrieve profile information about the authenticated user.

Section Two – OpenID Connect Protocol Specifics

2 ID Token

The ID token is a token used to identify an end-user to the client application and to provide data around the context of that authentication.

An ID token will be in the JSON Web Token (JWT) format. In most cases the ID token will be signed according to JSON Web Signing (JWS) specifications; however, depending on the client profile used, the verification of this signature may be optional.

Note: When the `id_token` is received from the token endpoint via a secure transport channel (i.e. via the Authorization Code grant type) the verification of the digital signature is optional.

2.1 ID Token decoded

The `id_token` JWT consists of three components, a header, a payload and the digital signature. Following the JSON Web Token (JWT) standard, these three sections are Base64url encoded and separated by periods (.).

Note: JWT and OpenID Connect assume base64url encoding/decoding. This is slightly different than regular base64 encoding. Refer to RFC4648 for specifics regarding base64 vs base64 URL safe encoding.

The following example describes how to manually parse a sample ID token provided below:

```
eyJhbGciOiJSUzI1NiIsImtpZCI6Imkwd25uIn0.eyJzdWIiOiJqb2UiLCJhdWQiOiJpbV
9vaWNfY2xpZW50IiwianRpIjoiaWY5MFNlNHdzY0ZoY3RVVDZEdHZiMiIsImIzcyI6Imh0
dHBzOlwvXC9sb2NhOGhvc3Q6OTAzMzIsIm1hdCI6MTM5NDA2MDg1MywiZXhwIjoxMzk0MD
YxMTUzLCJub25jZSI6ImU5NTdmZmJhLTlhNzgtNGVhOS04ZW5hLWFlOGM0ZWY5Yzg1NiIs

oT7DJi7Re0eSZDdstAdOKHwSvjZfR-OpdWSOmsrw0QVeI7oaIcehyKUFpPFDXDR0-
RsEzqno0yek-_U-Ui5EM-yv0PiaUOmJK1U-ws_C-fCplUFSE7SK-TrCwaOow4_7FN5L4i-
4NAa_WqgOjZPlOT8o3kKyTkBL7GdITL8rEe4BDK8L6mLqHJrFX4SsEduPk0CyHJSyKqzY
S2MEJlncocBBI4up5Y5g2BNEb0aV4VZwYjmrV9oOUC_yC1Fb4Js5Ry1t6P4Q8q_2ka5Oca
rlol88XH71MgPA2GnwSFGHBhccjpxhN7S46ubGPXRBNSnrPx6Ruor2cI46d9ARQ
```

Note: It is strongly recommended to make use of common libraries for JWT and JWS processing to avoid introducing implementation specific bugs.

The above JWT token is first split by periods (.) into three components:

2.1.1 JWT Header

Contains the algorithm and a reference to the appropriate public key if applicable:

Component	Value	Value Decoded
JWT Header	eyJhbGciOiJSUzI1NiIsImtpZCI6Imkwd25uIn0	{ "alg": "RS256", "kid": "i0wnn" }

2.1.2 JWT Payload

Contains the payload (in JSON) format. See below for id_token attribute descriptions.

Component	Value	Value Decoded
JWT Payload	eyJzdWIiOiJqb2UiLCJhdWQiOiJpbV9vaWNfY2xpZW50IiwianRpIjoidWY5MFNLNHdzY0ZoY3RVVDZEdHZiMiIsImIzcyI6Imh0dHBzO1wvXC9sb2NhOGhvc3Q6OTAzMzIsIm1hdCI6MTM5NDA2MDg1MywiZXhwIjoxMzk0MDYxMTUzLCJub25jZSI6ImU5NTdmZmJhLTlhNzgtNGVhOS04ZWZhLWFlOGM0ZWY5Yzg1NiIsImF0X2hhc2giOiJ3Zmd2bUU5VnhqQXVkc2w5bGM2VHFBIn0	{ "sub": "joe", "aud": "im_oic_client", "jti": "uf90SK4wscFhctUT6Dtvb2", "iss": "https://localhost:9031", "iat": 1394060853, "exp": 1394061153, "nonce": "e957ffba-9a78-4ea9-8eca-ae8c4ef9c856", "at_hash": "wfgvmE9VxjAuds19lc6TqA" }

2.1.3 Digital Signature

Base64 URL encoded signature of section 1 and 2 (period concatenated). The algorithm and key reference used to create and verify the signature is defined in the JWT Header.

Component	Value	Value Decoded
JWT Signature	lr4L-oT7Dji7Re0eSZDStAdOKHwSvjZfR-OpdWSOmsrw0QVeI7oaIcehyKUFpPFDXDR0-RsEzqno0yek-_U-Ui5EM-yv0PiaUOmJK1U-ws_C-fCplUFSE7SK-TrCwaOow4_7FN5L4i-4NAa_WqgOjZPlot8o3kKyTkBL7GdITL8rEe4BDK8L6mLqHJrFX4SsEduPk0CyHJSykRqzYS2MEJlncocBBI4up5Y5g2BNEb0aV4VZwYjmrV9oOUC_yC1Fb4Js5Rylt6P4Q8q_2ka5OcArlo188XH71MgPA2GnwSFGHBhccjpxhN7S46ubGPXRBnsnrPx6RuoR2cI46d9ARQ	N/A

2.2 ID Token Payload

The payload will contain claims relating to the authentication and identification of the user. Open ID Connect defines a set of rules to validate the integrity of the ID token. Additional checks may be performed by the client application depending on specific authentication requirements.

The following claims you can expect in an `id_token` and can use to determine if the authentication by the user was sufficient to grant them access to the application. (Refer to the OpenID Connect specifications to additional details on these attributes):

Claim	Description
<code>iss</code>	Issuer of the <code>id_token</code> (required)
<code>sub</code>	Subject of the <code>id_token</code> (ie the end-user's username) (required)
<code>aud</code>	Audience for the <code>id_token</code> (must match the <code>client_id</code> of the application) (required)
<code>exp</code>	Time the <code>id_token</code> is set to expire (UTC, Unix Epoch time) (required)
<code>iat</code>	Timestamp when the <code>id_token</code> was issued (UTC, Unix Epoch time) (required)
<code>auth_time</code>	Time the end-user authenticated (UTC, Unix Epoch time)
<code>nonce</code>	Nonce value supplied during the authentication request (required for implicit flow)
<code>acr</code>	Authentication context reference used to authenticate the user
<code>at_hash</code>	Hash of the OAuth2 access token when used with Implicit profile
<code>c_hash</code>	Hash of the OAuth2 authorization code when used with the hybrid profile

2.3 Validating the ID token payload

The ID token represents an authenticated user's session. As such, the token must be validated before an application can trust the contents of the ID token. For example, if a malicious attacker replayed a user's `id_token` that they had captured earlier, the application should detect that the token has been replayed or was used after it had expired and deny the authentication.

Refer to the OpenID Connect specifications for more information on security concerns. The specifications also include guidelines for validating an ID token (Core specification section 3.1.3.7). The general process would be as follows:

Step #	Test Summary
1	Decrypt the token (if encrypted)
2	Verify the issuer claim (iss) matches the OP issuer value
3	Verify the audience claim (aud) contains the OAuth2 client_id
4	If the token contain multiple audiences, then verify that an Authorized Party claim (azp) is present
5	If the azp claim is present, verify it matches the OAuth2 client_id
6, 7 & 8	Optionally verify the digital signature (required for implicit client profile) (see section 4.4)
9	Verify the current time is prior to the expiry claim (exp) time value
10	Client specific: Verify the token was issued within an acceptable timeframe (iat)
11	If the nonce claim (nonce) is present, verify that it matches the nonce passed in the authentication request
12	Client specific: Verify the Authn Context Reference claim (acr) value is appropriate
13	Client specific: If the authentication time claim (auth_time) present, verify it is within an acceptable range
14	If the implicit client profile is used, verify that the access token hash claim (at_hash) matches the hash of the associated access_token

2.4 Validating the ID token signature

Note: Signature validation is only required for tokens not received directly from the token endpoint (i.e. for the Implicit Client Profile). In other cases where the id_token is received directly by the client from the token endpoint over HTTPS, transport layer security should be sufficient to vouch for the integrity of the token.

The ID token is signed according to the JSON Web Signature (JWS) specification; algorithms used for signing are defined in the JSON Web Algorithm (JWA) specification. PingFederate 7.1 can support the following signing algorithms:

"alg" Value	Signature Method	Signing Key
NONE	No Digital Signature	N/A
HS256	HMAC w/ SHA-256 hash	Uses the client secret of the OAuth2 client
HS384	HMAC w/ SHA-384 hash	Uses the client secret of the OAuth2 client
HS512	HMAC w/ SHA-512 hash	Uses the client secret of the OAuth2 client
RS256	RSA PKCS v1.5 w/ SHA-256 hash	Public key available from the JWKS (see below)
RS384	RSA PKCS v1.5 w/ SHA-384 hash	Public key available from the JWKS (see below)
RS512	RSA PKCS v1.5 w/ SHA-512 hash	Public key available from the JWKS (see below)
ES256	ECDSA w/ P-256 curve and SHA-256 hash	Public key available from the JWKS (see below)
ES384	ECDSA w/ P-384 curve and SHA-384 hash	Public key available from the JWKS (see below)
ES512	ECDSA w/ P-521 curve and SHA-512 hash	Public key available from the JWKS (see below)

Note: RS256 is the default signature algorithm.

The basic steps to verify a digital signature involve retrieving the appropriate key to use for the signature verification and then performing the cryptographic action to verify the signature.

To validate the signature, take the JWT header and the JWT payload and join with a period. Validate that value against the third component of the JWT using the algorithm defined in the JWT header. Using the above ID token as an example:

Signed data (JWT Header + "." + JWT Payload):

```
eyJhbGciOiJSUzI1NiIsImtpZCI6Imkwd25uIn0.eyJzdWIiOiJqb2UiLCJhdWQiOiJpbV
9vaWNfY2xpZW50IiwianRpIjoidWY5MFNlNHdzY0ZoY3RVVDZEdHZiMiIsImIzcyI6Imh0
dHBzOlwvXC9sb2Nhbnhvc3Q6OTAzMSIsImIhdCI6MTM5NDA2MDg1MywiZXhwIjoxMzk0MD
YxMTUzLCJub25jZSI6ImU5NTdmZmJhLTlhNzgtNGVhOS04ZWZhLWFlOGM0ZWY5YzglNiIs
ImF0X2hhc2giOiJ3Zmd2bUU5VnhqQXVkc2w5bGM2VHFBIn0
```

Signature value to verify:

```
lr4L-oT7Dji7Re0eSZDStAdOKHwSvjZfR-OpdWSOmsrw0QVeI7oaIcehyKUfPpFDXDR0-
RsEzqno0yek-_U-Ui5EM-yv0PiaUOmJK1U-ws_C-fCplUFSE7SK-TrCwaOow4_7FN5L4i-
4NAa_WqgOjZPlOT8o3kKyTkBL7GdITL8rEe4BDK8L6mLqHJrFX4SsEduPk0CyHJSyKRqzY
S2MEJlncocBBI4up5Y5g2BNEb0aV4VZwYjmrV9oOUC_yC1Fb4Js5Ry1t6P4Q8q_2ka5Oca
rlo188XH7lMgPA2GnwSFGHBhccjpxhN7S46ubGPXRBNsnrPx6RuoR2cI46d9ARQ
```

Note: The actual implementation of the signing algorithm used to validate the signature will be implementation specific. It is recommended to use a published library to perform the signature verification.

For symmetric key signature methods, the client secret value for the OAuth2 client is used as the shared symmetric key. For this reason the client secret defined for the OAuth2 client must be of a large enough length to accommodate the appropriate algorithm (i.e. for a SHA256 hash, the secret must be at least 256 bits – 32 ASCII characters).

Asymmetric signature methods require the application to know the corresponding public key. The public key can be distributed out-of-band or can be retrieved dynamically via the JSON Web Key Set (JWKS) endpoint as explained below:

1. Determine the signing algorithm (alg) and the key identifier (kid) from the JWT header.

Using the sample JWT token above as an example, the following values are known:

Item	Value
OpenID Connect Issuer	https://localhost:9031
Signing algorithm (alg)	RS256
Key reference identifier (kid)	i0wnn

2. Query the OpenID configuration URL for the location of the JWKS:

HTTP Request
GET https://localhost:9031/.well-known/openid-configuration HTTP/1.1
Headers
<N/A>
Body
<N/A>

HTTP Response
HTTP/1.1 200 OK
Headers
Content-Type: application/json; charset=UTF-8
Body
<pre>{ "version": "3.0", "issuer": "https://localhost:9031", "authorization_endpoint": "https://localhost:9031/as/authorization.oauth2", "token_endpoint": "https://localhost:9031/as/token.oauth2", "userinfo_endpoint": "https://localhost:9031/idp/userinfo.openid", "jwks_uri": "https://localhost:9031/pf/JWKS", "scopes_supported": ["phone", "address", "email", "admin", "edit", "openid", "profile"], "response_types_supported": ["code", "token", "id_token", "code token", "code id_token", "token id_token", "code token id_token"], "subject_types_supported": ["public"], "id_token_signing_alg_values_supported": ["none", "HS256", "HS384", "HS512", "RS256", "RS384", "RS512", "ES256", "ES384", "ES512"], "token_endpoint_auth_methods_supported": ["client_secret_basic", "client_secret_post"], "claim_types_supported": ["normal"], "claims_parameter_supported": false, "request_parameter_supported": false, "request_uri_parameter_supported": false }</pre>

3. Parse the JSON to retrieve the `jwks_uri` value (bolded above) and make a request to that endpoint to retrieve the public key for key identifier `4oiu8` that was used to sign the JWT:

HTTP Request
GET https://localhost:9031/pf/JWKS HTTP/1.1
Headers
<N/A>
Body
<N/A>

HTTP Response
HTTP/1.1 200 OK
Headers
Content-Type: application/json; charset=UTF-8
Body
<pre>{ "keys": [{ "kty": "EC", "kid": "i0wnq", "use": "sig", "x": "AXYMGFO6K_R2E3RH42_5YTeGYgYTagLM-v3iaiNlPKFFvTh17CKQL_OKH5pEkj5U8mbel-0R1YrNuraRxtBztCVO", "y": "AaYUq27czYSrbFQUMo3jVK2hrW8KZ75KyE8dyYS-HOB9vUC4nMvoPGbu2hE_yBTLZLpuUvTOSSv150FLaBPhPLA2", "crv": "P-521" }, ... { "kty": "RSA", "kid": "i0wnn", "use": "sig", "n": "mdrLAp5GR8o5d5qbWWTYqNGuSXHTIE6w9HxV445oMACOWRuwlOGVZeKJQXHM9cs5Dm7iUfNVk4pJBttUxzcnhVCRf9tr20LJB7xAAqnFtzD7jBHARWbgJYR0p0JYVOA5jVzT9Sc-j4Gs5m8b-am2hKF93kA4fM8oeg18V_xeZf1lWWcxnW5YZwX9kjGBwbK-1tkapIar8K1WrsAsDDZLS_y7Qp0S83fAPgubFGYdST71s-B4bvsjCgl30a2W-je9J6jg2bYxZeJf982dzHFqVQF7KdF4n5UGFAvNMRZ3xVoV4JzHDg4xe_KJE-gOn-_wla06R8xWcedZjTmDhqqvUw", "e": "AQAB" }, ...] }</pre>

We now have the modulus (n) and the exponent (e) of the public key. This can be used to create the public key and validate the signature.

Note: The public key can be stored in secure storage (i.e. in the keychain) to be used for verification of the id_token when a user is offline.

2.5 Validating the token hashes (at_hash, c_hash)

In specific client profiles, a specific hash is included in the id_token to use to verify that the associated token was issued along with the id_token. For example, when using the implicit client profile, an at_hash value is included in the id_token that provides a means to verify that the access_token was issued along with the id_token.

The following example uses the `id_token` above and associated `access_token` to verify the `at_hash` `id_token` claim:

Item	Value
Signing algorithm (alg)	RS256
at_hash value	wfgvmE9VxjAudsl9lc6TqA
OAuth2 access_token	dNZX1hEZ9wBCzNL40Upu646bdzQA

1. Hash the octets of the ASCII representation of the access token (using the hash algorithm specified in the JWT header (i.e. for this example, RS256 uses a SHA-256 hash)):

```
SHA256HASH("dNZX1hEZ9wBCzNL40Upu646bdzQA") =
```

```
c1f82f98 4f55c630 2e76c97d 95ce93a8
9a5d61f7 dc99b9ad 37dc12b3 7231ff9d
```

2. Take the left-most half of the hashed access token and Base64url encode the value.

```
Left-most half: c1f82f98 4f55c630 2e76c97d 95ce93a8
```

```
Base64urlencode([0xC1, 0xF8, 0x2F, 0x98, 0x4F, 0x55, 0xC6, 0x30,
0x2E, 0x76, 0xC9, 0x7D, 0x95, 0xCE, 0x93, 0xA8]) =
"dNZX1hEZ9wBCzNL40Upu646bdzQA"
```

3. Compare the `at_hash` value to the base64 URL encoded left-most half of the access token hash bytes.

at_hash value	dNZX1hEZ9wBCzNL40Upu646bdzQA
left-most half value	dNZX1hEZ9wBCzNL40Upu646bdzQA
Result	VALID

3 UserInfo Claims & Endpoint

The OpenID Connect UserInfo endpoint is used by an application to retrieve profile information about the identity that authenticated. Applications can use this endpoint to retrieve profile information, preferences and other user-specific information.

The OpenID Connect profile consists of two components:

- Claims describing the end-user
- UserInfo endpoint providing a mechanism to retrieve these claims

3.1 UserInfo Claims

The UserInfo endpoint will present a set of claims based on the OAuth2 scopes presented in the authentication request.

OpenID Connect defines five scope values that map to a specific set of default claims. PingFederate allows you to extend the “profile” scope via the “OpenID Connect Policy Management” section of the administration console. Multiple policy sets can be created and associated on a per-client basis.

Connect Scope	Returned Claims
openid	Indicates this is an OpenID Connect request. Returns subject (same as in ID token)
profile	name, family_name, given_name, middle_name, nickname, preferred_username, profile, picture, website, gender, birthdate, zoneinfo, locale, updated_at, *custom attributes
address	address
email	email, email_verified
phone	phone_number, phone_number_verified

Note: If a scope is omitted (i.e. the “email” scope is not present), the claim “email” will not be present in the returned claims. For custom profile attributes, prefix the value to avoid clashing with the default claim names.

Note: If an OpenID Connect id_token is requested without an OAuth2 access token (i.e. when using the implicit “response_type = id_token” request), the claims will be returned in the id_token rather than the UserInfo endpoint.

3.2 Sample UserInfo Endpoint Request

Once the client application has authenticated a user and is in possession of an access token, the client can then make a request to the UserInfo endpoint to retrieve the requested attributes about a user. The request will include the access token presented using a method described in RFC6750.

The UserInfo endpoint provided by PingFederate is located at:

```
https://<pingfederate_base_url>/idp/userinfo.openid
```

Note: The UserInfo endpoint can also be determined by querying the OpenID Connect configuration information endpoint: `https://<pingfederate_base_url>/.well-known/openid-configuration`

Example client request to the UserInfo endpoint:

HTTP Request
GET https://pf.company.com:9031/idp/userinfo.openid HTTP/1.1
Headers
Authorization: Bearer <access token>
Body
<N/A>

Example OpenID Connect Provider (OP) response:

HTTP Response
HTTP/1.1 200 OK
Headers
Content-Type: application/json;charset=UTF-8
Body
{ "sub": "mpavlich", "family_name": "Pavlich", "given_name": "Matthew", "nickname": "Pav", ...[additional claims]... }

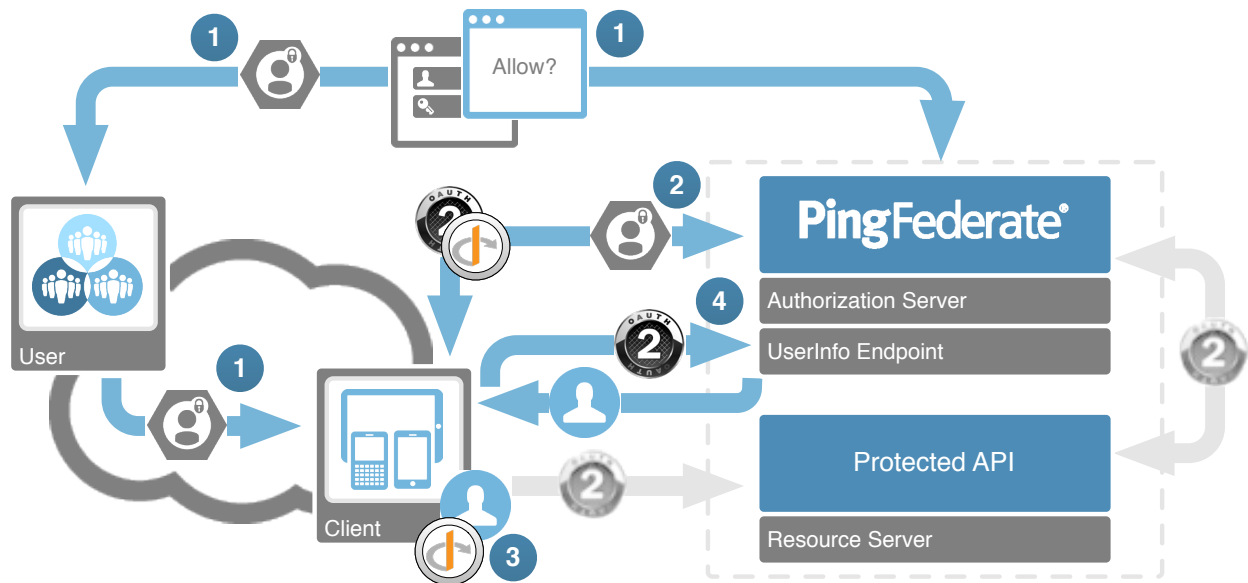

3.3 Security considerations

Before the client application can trust the values returned from the UserInfo endpoint (i.e. as a check for token substitution attack), the client must verify that the “sub” claim returned from the UserInfo endpoint request matches the subject from the id_token.

Section Three – OpenID Connect Profile Walkthroughs

4 OpenID Connect Basic Client Profile

This section walks through an example authentication using the OpenID Connect Basic Client Profile. This will step through requesting the authentication of a user, receiving the OpenID Connect id_token (step 1 through 3 below) and then querying the UserInfo endpoint to retrieve profile information about the user (step 4).

For the purposes of this example, this example assumes PingFederate 7.1 installed with the OAuth2 Playground. The following configuration will be used:

Item	Value
PingFederate server base URL	https://localhost:9031
OAuth2 client_id	ac_oic_client
OAuth2 client_secret	abc123DEFghijklmnop4567rstuvwxyzZYXWUT8910SRQPOnmlijhoauthplayground application
Application callback URI	https://localhost:9031/OAuthPlayground/case1A-callback.jsp

Note: For native mobile applications, the callback URI may be a non-http URI. This is configured in your application settings and will cause the mobile application to be launched to process the callback.

4.1 Step 1: Authenticate the End-User and Receive Code

The initial user authentication request follows the OAuth2 Authorization Grant Type flow. To initiate the OpenID Connect process, the user will be redirected to the OAuth2 authorization endpoint with the “openid” scope value. Additional scope values can be included to return specific profile scopes.

The request is made to the authorization endpoint with the following parameters:

Parameter	Value
client_id	ac_oic_client
response_type	code
redirect_uri	https://localhost:9031/OAuthPlayground/case1A-callback.jsp
scope	openid profile

The client will then form the authorization URL and redirect the user to this URL via their user agent (e.g. browser). This can be performed in different ways depending on the client and the desired user experience. For example, a web application can just issue a HTTP 302 redirect to the browser and redirect the user to the authorization URL. A native mobile application may launch the mobile browser and open the authorization URL.

The authorization URL using the values above would be:

```
https://localhost:9031/as/authorization.oauth2?client_id=ac_oic_client&response_type=code&redirect_uri=https://localhost:9031/OAuthPlayground/case1A-callback.jsp&scope=openid%20profile
```

The user will then be sent through the authentication process (e.g. prompted for their username/password at their IDP, authenticated via Kerberos or x509 certificate etc).

Once the user authentication (and optional consent approval) is complete, the authorization code will be returned as a query string parameter to the redirect_uri specified in the authorization request.

HTTP Request	
GET	https://localhost:9031/OAuthPlayground/Case1A-callback.jsp?code=ABC...XYZ
HTTP/1.1	
Headers	
<N/A>	
Body	
<N/A>	

Note: An error condition from the authentication / authorization process would be returned to this callback URI with “error” and “error_description” parameters.

4.2 Step 2: Exchange the authorization code for the tokens

Following the Authorization Code grant type defined in the OAuth 2.0 protocol, the application will then swap this authorization code at the token endpoint for the OAuth2 token(s) and the OpenID Connect ID Token as follows:

HTTP Request	
POST https://localhost:9031/as/token.oauth2 HTTP/1.1	
Headers	
Content-Type:	application/x-www-form-urlencoded
Body	
grant_type=authorization_code&client_id=ac_oic_client&client_secret=abc123DEFghijklmnop4567rstuvwxyzZYXWUT8910SRQPOnmlijhoauthplaygroundapplication&code=ABC...XYZ&redirect_uri=https://localhost:9031/OAuthPlayground/case1A-callback.jsp	

Note: As the redirect_uri was specified in the original authorization request, it is required to be sent in the token request.

The token endpoint will respond with a JSON structure containing the OAuth2 access token, refresh token (if enabled in the OAuth client configuration) and the OpenID Connect ID token:

HTTP Response	
HTTP/1.1 200 OK	
Headers	
Content-Type:	application/json; charset=UTF-8
Body	
{ "token_type": "Bearer", "expires_in": 7199, "refresh_token": "BBB...YYY", "id_token": "eyJhbGciOiJSUzI1NiIsImtpZCI6IjRvaXU4In0.eyJzdWIiOiJuZnlnmZSI6ImF1ZCI6ImFjX29pY19jbGllbnQiLCJqdGkiOiJIR1AwdnlxbmgwOVBJQ3MzenBHbUVsIiwiaXNzIjoiaHR0cHM6XC9cL3Nzby5tZXIjbnG91ZC5uZXQ6OTAzMSIsImhhdCI6MTM5MzczMDM4MCwiZXhwIjozNzNzMWwNjgwZQ.EQeAm84Xj2lekxUMSK9H3BvoC1511JV1TWHCyQQ7vTnXcuvZYdBHE9_OpIr9gD5OHj0DrOhwVEjKUqvwGhZBPNEueeY8bUgkTfIBKzUUJETSea01U8uH9Td0QYv7q3rRfurLhrpzubFbAIfjPOiv8jxgBjMyGEedPJ7aXtBwP_cr2RxMUzg_iBRA4cD8c4PwEOROr0T-xKnwZcocDZs_rYAOHf1jLPgO2tX8BBEPJfQUUG46U1K4hSgo7LP3zru4BDE2wNbZyOhb2keeLjetNq2ES33YthNÜ9dkmHUGbtoD-Ji7kYnMaij3ta1OyLSB_HB-NbhQCKvjm4GT9ocm0w", "access_token": "AAA...ZZZ" }	

The application now has multiple tokens to use for authentication and authorization decisions:

Token	Value
access_token	AAA...ZZZ
refresh_token	BBB...YYY
id_token	eyJhbGciOiJSUzI1NiIsImtpZCI6IjRvaXU4In0.eyJzdWIiOiJuZnlnZSIsImF1ZCI6ImFjX29pY19jbGllbnQiLCJqdGkiOiJIRlAwdnlxbmgwOVBJQ3MzenBHbUVsIiwiaXNzIjoiaHR0cHM6XC9cL3Nzby5tZX1jbG91ZC5uZXQ6OTAzMzIsImhhdCI6MTM5MzczMDM4MCwiZXhwIjoxMzkzNzMwNjgwZjQ.EQeAm84Xj2lekxUMSK9H3BvoC1511JV1TWHCyQQ7vTnXcuvZYdBHE9_OpIr9gD5OHjoDrOhwVEjKUqvwGhzBPNEueeY8bUgkTfIBKzUUJETSeaOlU8uH9Td0QYv7q3rRfurLhrpzbFbAIfjPOiv8jxgBjMyGEdPJ7aXtBwP_cr2RxMUzg_iBRA4cD8c4PwEOROr0T-xKnwZcocDZs_rYAOHFljLPgO2tX8BBEPJfQUUUG46U1K4hSqo7LP3zru4BDE2wNbZyOhb2keeLjetNq2ES33YthNU9dkmHUGbtoD-Ji7kYnMaij3ta1OyLSB_HB-NbhQCKvj4GT9ocm0w

4.3 Step 3: Validate the id_token

The next step is to parse the id_token, and validate the contents. Note, that as the id_token was received via a direct call to the token endpoint, the verification of the digital signature is optional.

Firstly, decode both the header and payload components of the JWT:

Component	Value	Value Decoded
Header	eyJhbGciOiJSUzI1NiIsImtpZCI6IjRvaXU4In0	{ "alg": "RS256", "kid": "4oiu8" }
Payload	eyJzdWIiOiJuZnlnZSIsImF1ZCI6ImFjX29pY19jbGllbnQiLCJqdGkiOiJIRlAwdnlxbmgwOVBJQ3MzenBHbUVsIiwiaXNzIjoiaHR0cHM6XC9cL3Nzby5tZX1jbG91ZC5uZXQ6OTAzMzIsImhhdCI6MTM5MzczMDM4MCwiZXhwIjoxMzkzNzMwNjgwZjQ	{ "sub": "nfyfe", "aud": "ac_oic_client", "jti": "HGP0vyqnh09PcCs3zpGmEl", "iss": "https://localhost:9031", "iat": 1393730380, "exp": 1393730680 }

Now we follow the guidelines in the OpenID Connect specifications (Core specification section 3.1.3.7) for ID Token Validation (see 2.3 for details on validating the id_token)

Step #	Test Summary	Result
1	Decrypt the token (if encrypted)	Token not encrypted, skip test.
2	Verify the issuer claim (iss) matches the OP issuer value	Valid
3	Verify the audience claim (aud) contains the OAuth2 client_id	Valid
4	If the token contain multiple audiences, then verify that an Authorized Party claim (azp) is present	Only one audience, skip test.
5	If the azp claim is present, verify it matches the OAuth2 client_id	Not present, skip test.
6, 7 & 8	Optionally verify the digital signature (required for implicit client profile) (see section 4.4)	TLS security sufficient, skip test.
9	Verify the current time is prior to the expiry claim (exp) time value	Valid
10	Client specific: Verify the token was issued within an acceptable timeframe (iat)	Valid
11	If the nonce claim (nonce) is present, verify that it matches the nonce passed in the authentication request	Nonce was not sent in initial request, skip test.
12	Client specific: Verify the Authn Context Reference claim (acr) value is appropriate	No acr value present, skip test.
13	Client specific: If the authentication time claim (auth_time) present, verify it is within an acceptable range	No auth_time present, skip test.

The results of the ID token validation are sufficient to trust the id_token and the user can be considered “authenticated”.

4.4 Step 4: Retrieve the user profile

We now have an authenticated user; the next step is to request the user profile attributes so that we can personalize their application experience and render the appropriate content to the user. This is achieved by requesting the contents of the UserInfo endpoint:

HTTP Request
GET https://localhost:9031/oid/userinfo.openid HTTP/1.1
Headers
Authorization: Bearer AAA...ZZZ
Body
<N/A>

The response from the UserInfo endpoint will be a JSON structure with the requested OpenID Connect profile claims:

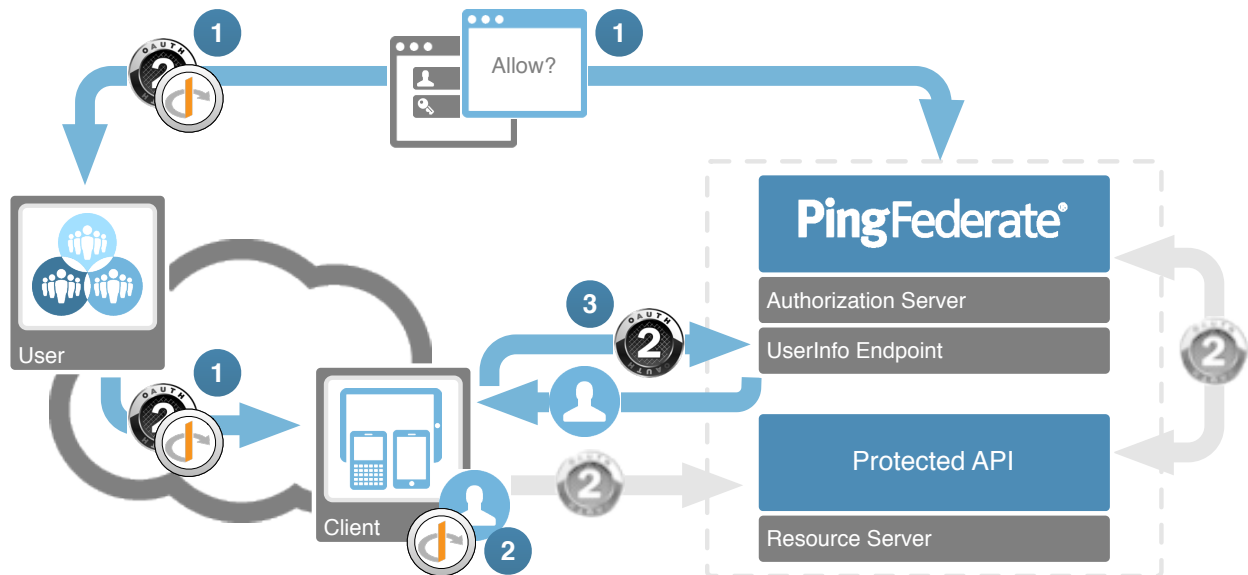

HTTP Response
HTTP/1.1 200 OK
Headers
Content-Type: application/json; charset=UTF-8
Body
<pre>{ "sub": "nfyfe", "family_name": "Fyfe", "given_name": "Nathan", "nickname": "Nat", ...[additional claims]... }</pre>

Before we can be confident the response to the UserInfo reflects the authenticated user, we must also check that the subject (“sub” claim) returned from the UserInfo endpoint matches the authenticated user we received in the id_token.

In this case, the “sub” claim in both the UserInfo response and the id_token match so we can use the values in the UserInfo response for our application needs.

5 OpenID Connect Implicit Client Profile

This section provides an example of using OpenID Connect Implicit Client Profile to retrieve an OpenID Connect id_token, validate the contents (steps 1 and 2 in the diagram below) and then query the UserInfo endpoint to retrieve profile information about the user (step 3).

For the purposes of this example, the following configuration will be used:

Item	Value
PingFederate server base URL	https://localhost:9031
OAuth2 client_id	im_oic_client
OAuth2 client_secret	<None>
Application callback URI	https://localhost:9031/OAuthPlayground/case2A-callback.jsp

5.1 Step 1: Authenticate the End-User and Request Token

The initial user authentication request follows the OAuth2 Implicit Grant Type flow. To initiate the OpenID Connect process, the user will be redirected to the OAuth2 authorization endpoint

The request is made to the authorization endpoint with the following parameters:

Parameter	Value
client_id	im_oic_client
response_type	token id_token
redirect_uri	https://localhost:9031/OAuthPlayground/case2A-callback.jsp
scope	openid profile
nonce	cba56666-4b12-456a-8407-3d3023fa1002

Note: As the implicit flow transports the access token and ID token via the user agent (i.e. web browser), this flow requires additional security precautions to mitigate any token modification / substitution.

As for the Basic Client Profile, the client can redirect the user in different ways depending on the client and the desired user experience. For example, a web application can just issue a HTTP 302 redirect to the browser and redirect the user to the authorization URL. A native mobile application may launch the mobile browser and open the authorization URL.

Note: To mitigate replay attacks, a nonce value must be included to associate a client session with an id_token. The client must generate a random value associated with the current session and pass this along with the request. This nonce value will be returned with the id_token and must be verified to be the same as the value provided in the initial request.

```
https://localhost:9031/as/authorization.oauth2?client_id=im_oic_client&response_type=token%20id_token&redirect_uri=https://localhost:9031/OAuthPlayground/case2A-callback.jsp&scope=openid%20profile&nonce=cba56666-4b12-456a-8407-3d3023fa1002
```

Again, like the Basic Client Profile, the user will then be sent through the authentication process (e.g. prompted for their username/password at their IDP, authenticated via Kerberos or x509 certificate, etc). Once the user authentication (and optional consent approval) is complete, the tokens will be returned as a fragment parameter to the redirect_uri specified in the authorization request.

HTTP Request

```
GET https://localhost:9031/OAuthPlayground/Case2A-callback.jsp
#token_type=Bearer&expires_in=7199&id_token=eyJhbGciOiJSUzI1NiIsImtpZCI6IjRvaXU4In0.eyJzdWIiOiJuZnlnMzSI6ImF1ZCI6Im1tX29pY19jbGllbnQiLCJqdGkiOiJUOU4xUklkRkVzUE45enU3ZWw2eng2IiwiaXNzIjoiaHR0cHM6XC9cL3Nzby5tZX1jbG91ZC5uZXQ6OTAzMStSIm1hdCI6MTM5Mzc5NzA3MSwiZXhwIjoxMzgzNzY3MzcxLCJub25jZSI6ImNiYTU2NjY2LTRiMTItNDU2YS04NDA3LTNkMzAyM2ZhMTAwMiIsImF0X2hhc2giOiJrdHFvZVBhc2praVY5b2Z0X3o5NnJBIn0.g1Jc9DohWFfFG3ppWfvW16ib6YBaONC5VMs8J61i5j5QLieY-mBEeVi1D3vr5IFWCfivY4hZcHtoJHgZklqCumkAMDymlGX-IGA7yFU8LOjUdR4I1CP1ZxZ_vhqr_0gQ9pCFKDkiOv1LVv5x3YgAdhHhpZhXK6rWxojg2RddzvZ9Xi5u2V1UZ0jukwyG2d4PRzDn7WoRNDGwYOEt4qY7lv_NO2TY2eAk1P-xYBWu0b9FBElapnstqbZgAXdndNs-Wqp4gyQG5D0owLzxPPerR9MnpQfgNcai-PlWI_UrvoopKNbX0ai2zfkQ-qh6Xn8zgkiaYDHZq4gzwrFwazaqA&access_token=b5bU8whkHeD6k9KQK7X61MJrdVtV
HTTP/1.1
```

Headers

<N/A>

Body

<N/A>

Note: An error condition from the authentication / authorization process would be returned to this callback URI with “error” and “error_description” parameters.

The application now has multiple tokens to use for authentication and authorization decisions:

Token	Value
access_token	b5bU8whkHeD6k9KQK7X61MJrdVtV
id_token	eyJhbGciOiJSUzI1NiIsImtpZCI6IjRvaXU4In0.eyJzdWIiOiJuZnlnMzSI6ImF1ZCI6Im1tX29pY19jbGllbnQiLCJqdGkiOiJUOU4xUklkRkVzUE45enU3ZWw2eng2IiwiaXNzIjoiaHR0cHM6XC9cL3Nzby5tZX1jbG91ZC5uZXQ6OTAzMStSIm1hdCI6MTM5Mzc5NzA3MSwiZXhwIjoxMzgzNzY3MzcxLCJub25jZSI6ImNiYTU2NjY2LTRiMTItNDU2YS04NDA3LTNkMzAyM2ZhMTAwMiIsImF0X2hhc2giOiJrdHFvZVBhc2praVY5b2Z0X3o5NnJBIn0.g1Jc9DohWFfFG3ppWfvW16ib6YBaONC5VMs8J61i5j5QLieY-mBEeVi1D3vr5IFWCfivY4hZcHtoJHgZklqCumkAMDymlGX-IGA7yFU8LOjUdR4I1CP1ZxZ_vhqr_0gQ9pCFKDkiOv1LVv5x3YgAdhHhpZhXK6rWxojg2RddzvZ9Xi5u2V1UZ0jukwyG2d4PRzDn7WoRNDGwYOEt4qY7lv_NO2TY2eAk1P-xYBWu0b9FBElapnstqbZgAXdndNs-Wqp4gyQG5D0owLzxPPerR9MnpQfgNcai-PlWI_UrvoopKNbX0ai2zfkQ-qh6Xn8zgkiaYDHZq4gzwrFwazaqA

Note: Because the implicit grant involves these tokens being transmitted via the user agent, these tokens cannot be kept confidential; therefore a refresh_token cannot be issued using this flow.

5.2 Step 2: Validate the id_token

The next step is to parse the id_token and validate the contents. Note, that as the id_token was received via the user agent, rather than directly from the token endpoint, the verification of the digital signature is required to detect any tampering with the id_token.

Firstly, decode both the header and payload components of the JWT:

Component	Value	Value Decoded
Header	eyJhbGciOiJSUzI1NiIsImtpZCI6IjRvaXU4In0	{ "alg": "RS256", "kid": "4oiu8" }
Payload	eyJzdWIiOiJuZnlmZSIsImF1ZCI6ImltX29pY19jbGllbnQiLCJqdGkiOiJUUOU4xUklkRkVzUE45enU3ZWw2eng2IiwiaXNzIjoiaHR0cHM6XC9cL3Nzby5tZXljbG91ZC5uZXQ6OTAzMSIsIm1hdCI6MTM5MzczNzA3MSwiZXhwIjoxMzcxMzcxLCJub25jZSI6ImNiYTU2NjY2LTJhMTI0NDU2YS04NDA3LTNkMzAyM2ZhMTAwMiIsImF0X2hhc2giOiJrdHFvZVBhc2praVY5b2Z0X3o5NnJBIn0	{ "sub": "nfyfe", "aud": "im_oic_client", "jti": "T9N1RIdFEsPN9zu7el6zx6", "iss": "https://localhost:9031", "iat": 1393737071, "exp": 1393737371, "nonce": "cba56666-4b12-456a-8407-3d3023fa1002", "at_hash": "ktqoePasjkiV9oft_z96rA" }

Now we follow the guidelines in the OpenID Connect specifications (Core specification section 3.1.3.7 also taking into consideration section 3.2.2.11) for ID Token Validation:

Step #	Test Summary	Result
1	Decrypt the token (if encrypted)	Token not encrypted, skip test.
2	Verify the issuer claim (iss) matches the OP issuer value	Valid
3	Verify the audience claim (aud) contains the OAuth2 client_id	Valid
4	If the token contain multiple audiences, then verify that an Authorized Party claim (azp) is present	Only one audience, skip test.
5	If the azp claim is present, verify it matches the OAuth2 client_id	Not present, skip test.
6, 7 & 8	Optionally verify the digital signature (required for implicit client profile) (see section 4.4)	Verify signature as per section 2.4
9	Verify the current time is prior to the expiry claim (exp) time value	Valid
10	Client specific: Verify the token was issued within an acceptable timeframe (iat)	Valid
11	If the nonce claim (nonce) is present, verify that it matches the nonce passed in the authentication request	Valid. Nonce matches.
12	Client specific: Verify the Authn Context Reference claim (acr) value is appropriate	No acr value present, skip test.
13	Client specific: If the authentication time claim (auth_time) present, verify it is within an acceptable range	No auth_time present, skip test.

5.3 Step 3: Retrieve the user profile

We now have an authenticated user. The next step is to request the user profile attributes so that we can personalize their app experience and render the appropriate content to the user. This is achieved by requesting the claims from the UserInfo endpoint.

Accessing the UserInfo endpoint requires that we use the access token issued along with the authorization request. As the implicit flow transports the access token using the user agent, there is the threat of tokens being substituted during the authorization process. Before using the access token, the client should validate the at_hash value in the id_token to ensure the received access token was issued alongside the id_token.

To validate the at_hash value, see section 2.5. Once the at_hash is verified, the client can then use the access token to request the user profile:

HTTP Request
GET https://localhost:9031/idp/userinfo.openid HTTP/1.1
Headers
Authorization: Bearer b5bU8whkHeD6k9KQK7X6lMJrdVtV
Body
<N/A>

The response from the UserInfo endpoint will be a JSON structure with the requested OpenID Connect profile claims:

HTTP Response
HTTP/1.1 200 OK
Headers
Content-Type: application/json; charset=UTF-8
Body
{ "sub": "nfyfe", "family_name": "Fyfe", "given_name": "Nathan", "nickname": "Nat", ...[additional claims]... }

Before we can be confident the response to the UserInfo reflects the authenticated user, we must also check that the subject (“sub” claim) returned from the UserInfo endpoint matches the authenticated user we received in the id_token.

In this case, the “sub” claim in both the UserInfo response and the id_token match, so we can use the values in the UserInfo response for our application needs.
